### Introduction

The T15W single output series offer 15 watts of output power from a 2.00 X 1.00 X 0.40 inch package. The T15W single output series with 4:1 ultra wide input voltage of 9~36VDC, 18~75VDC. The T15W single output series features 1600VDC of isolation, short circuit and over voltage protection, as well as six sided shielding. All models are particularly suited to telecommunications, industrial, mobile telecom and test equipment applications.

### DC/DC Converter Features

Single output current to 4.5A
15 watts maximum output power
4:1 ultra wide input power range of 9~36VDC and 18~75VDC
Six-sided continuous shield
Case grounding
High efficiency up to 88%
Low profile 2.00 x 1.00 x 0.40 inch (50.8 x 25.4 x 10.2 mm)
Fixed switching frequency
RoHS Directive compliant
No minimum load
Input to output isolation 1600VDC, min
Operating case temperature range 105°C max
Input under-voltage protection
Output over-voltage protection
Over-current protection, auto-recovery
Output short circuit protection
Remote on/off

### Options

Heat-sink available for extended operation
Remote on/off logic configuration

### Input Source Impedance

The power module should be connected to a low impedance input source. Highly inductive source impedance can affect the stability of the power module. Input external L-C filter is recommended to minimize input reflected ripple current. The inductor is simulated source impedance of  $12\mu\text{H}$  and capacitor is Nippon chemi-con KZE series  $100\mu\text{F}/100\text{V}$ . The capacitor must as close as possible to the input terminals of the power module for lower impedance.

### Output Over Current Protection

When excessive output currents occur in the system, circuit protection is required on all power supplies. Normally, overload current is maintained at approximately 150 percent of rated current for T15W-S SERIES.

Hiccup-mode is a method of operation in a power supply whose purpose is to protect the power supply from being damaged during an over-current fault condition. It also enables the power supply to restart when the fault is removed. There are other ways of protecting the power supply when it is over-loaded, such as the maximum current limiting or current foldback methods.

One of the problems resulting from over current is that excessive heat may be generated in power devices, especially MOSFET and Schottky diodes and the temperature of those devices may exceed their specified limits. A protection mechanism has to be used to prevent those power devices from being damaged.

The operation of hiccup is as follows. When the current sense circuit sees an over-current event, the controller shuts off the power supply for a given time and then tries to start up the power supply again. If the overload condition has been removed, the power supply will start up and operate normally, otherwise, the controller will see another over-current event and shut off the power supply again, repeating the previous cycle. Hiccup operation has none of the drawbacks of the other two protection methods, although its circuit is more complicated because it requires a timing circuit. The excess heat due to overload lasts for only a short duration in the hiccup cycle, hence the junction temperature of the power devices is much lower.

The hiccup operation can be done in various ways. For example, one can start hiccup operation any time an over-current event is detected, or prohibit hiccup during a designated start-up is usually larger than during normal operation and it is easier for an over-current event is detected, or prohibit hiccup during a designated start-up interval (usually a few milliseconds). The reason for the latter operation is that during start-up, the power supply needs to provide extra current to charge up the output capacitor. Thus the current demand during start-up is usually larger than during normal operation and it is easier for an over-current event to

occur. If the power supply starts to hiccup once there is an over-current, it might never start up successfully. Hiccup mode protection will give the best protection for a power supply against over current situations, since it will limit the average current to the load at a low level, so reducing power dissipation and case temperature in the power devices.

### Output Over Voltage Protection

The output over-voltage protection consists of output Zener diode that monitors the voltage on the output terminals. If the voltage on the output terminals exceeds the over-voltage protection threshold, then the Zener diode clamps the output voltage.

### Short Circuitry Protection

Continuous, hiccup and auto-recovery mode. During short circuit, converter still shut down. The average current during this condition will be very low and the device can be safety in this condition.

### Thermal Consideration

The power module operates in a variety of thermal environments. However, sufficient cooling should be provided to help ensure reliable operation of the unit. Heat is removed by conduction, convection, and radiation to the surrounding Environment. Proper cooling can be verified by measuring the point as the figure below. The temperature at this location should not exceed  $105^{\circ}\text{C}$ . When Operating, adequate cooling must be provided to maintain the test point temperature at or below  $105^{\circ}\text{C}$ . Although the maximum point Temperature of the power modules is  $105^{\circ}\text{C}$ , you can limit this temperature to a lower value for extremely high reliability.

Remote On/Off Control

The Remote CTRL Pin is controlled DC/DC power module to turn on and off, the user must use a switch to control the logic voltage high or low level of the pin referenced to -INPUT. The switch can be open collector transistor, FET and Photo-Couple. The switch must be capable of sinking up to 0.5mA at low-level logic voltage. High-level logic of the CTRL pin signal maximum voltage is allowable leakage current of the switch at 12V is 0.5mA.

Remote ON/OFF implementation circuits

Isolated-Closure Remote On/Off

Level Control Using TTL Output

Level Control Using Line Voltage

There are two remote control options available, positive logic and negative logic.

a. The Positive logic structure turned on of the DC/DC module when the CTRL pin is at high-level logic and low-level logic is turned off it.

When T15W module is turned off at Low-level logic

When T15W module is turned on at High-level logic

b. The Negative logic structure turned on of the DC/DC module when the CTRL pin is at low-level logic and turned off when at high-level logic.

When T15W module is turned on at Low-level logic

When T15W module is turned off at High-level logic

Heat-sink

Equip Heat-sink (7G-0020C-F) for lower temperature and higher reliability of the module. Considering space and air-flow is the way to choose which heat-sink is needed.

Mechanical Data

### Safety and Installation Instruction

#### Fusing Consideration

Caution: This power module is not internally fused. An input line fuse must always be used.

This encapsulated power module can be used in a wide variety of applications, ranging from simple stand-alone operation to an integrated part of sophisticated power architecture. To maximum flexibility, internal fusing is not included, however, to achieve maximum safety and system protection, always use an input line fuse. The safety agencies require a slow-blow fuse with maximum rating of 5A. Based on the information provided in this data sheet on Inrush energy and maximum dc input current, the same type of fuse with lower rating can be used. Refer to the fuse manufacturer's data for further information.

### MTBF and Reliability

The MTBF of T15W SINGLE-SERIES of DC/DC converters has been calculated using MIL-HDBK 217F @Ta=25°C, FULL LOAD. The resulting figure for MTBF is  $2.430 \times 10^6$  hours.

**Recommended external EMI filter for EN55022 Class A**
